Objective

Research question

- *Understand the impact of short-term temperature and relative humidity changes in indoor air supply on the indoor climate near objects.*

Comsol Multiphysics is used to research the effect of fluctuating conditioned supply air on the indoor climate near objects in an exhibition room.

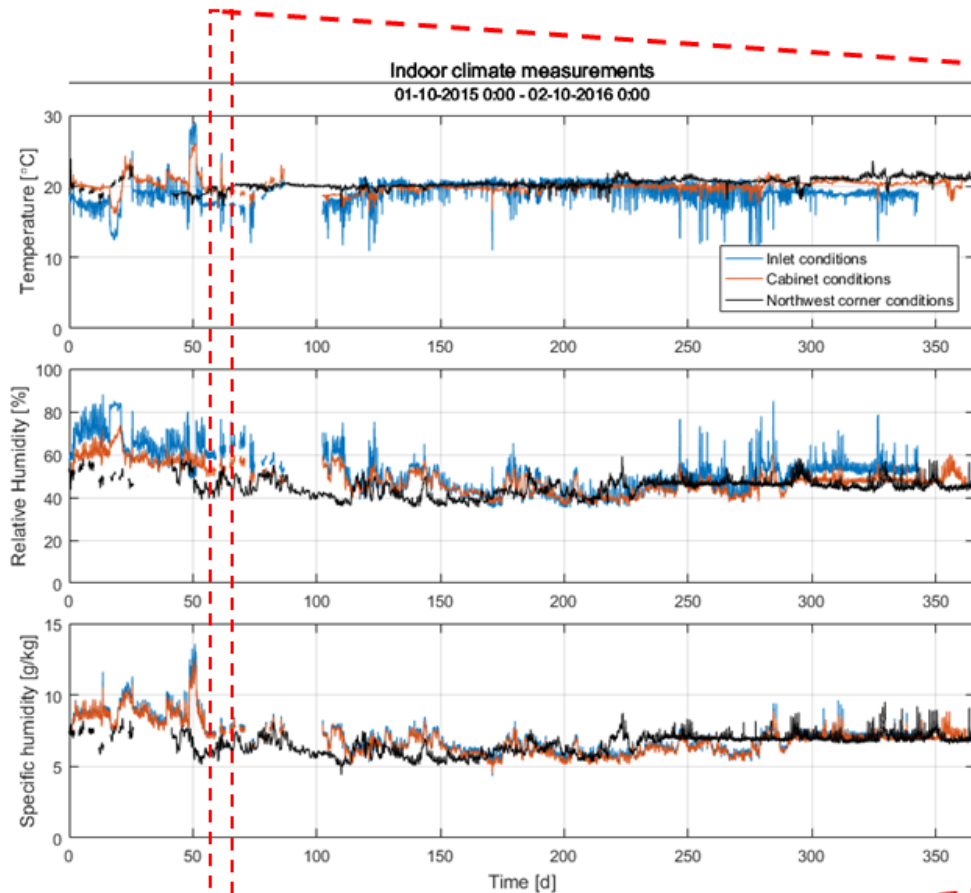

Method

Experimental

Case study Amsterdam Museum

- 15th century building
- Mixed collection
- HVAC since 2007
- Measurements of T_i , T_s , RH_i

Method

Numerical

- Heat transfer in fluids
- Moisture transfer in air
- Non-isothermal flow (k - ϵ turbulence model)

Method

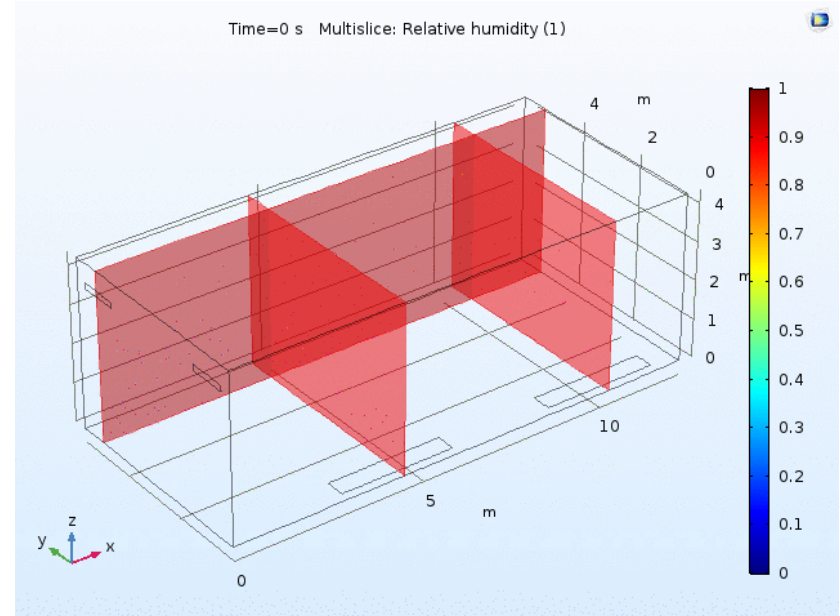

Numerical

- Grid
 - Fluid dynamics normal element size
 - Inlet/outlet boundaries restricted element size $< 0.1\text{m}$
- Boundary Conditions
 - Inlet: step function
 - Walls: constant T

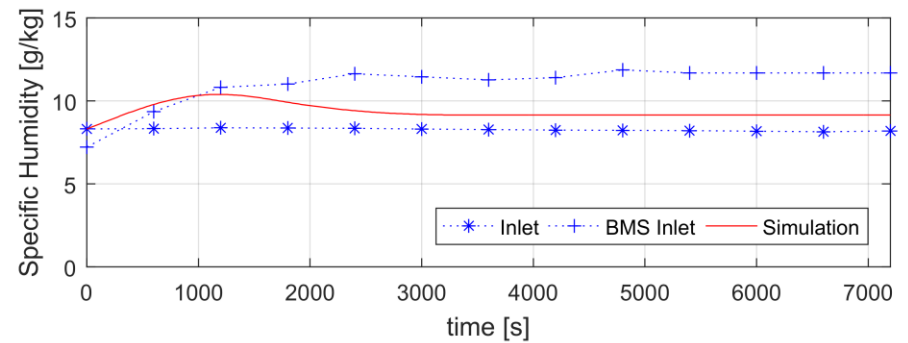

Results

Transient simulation

Validation

Results

Validation

Conclusions

Findings

- It is possible to use COMSOL Multiphysics as computational tool for indoor environment modelling influenced by HVAC climate control.
- The outcome is valuable for locating critical areas in an exhibition rooms and could be of help while staging a museum exhibition, or evaluating novel climate control strategies.

Model limitations

- The model is not yet adequately validated for this case study.
- It takes quite some computational effort to perform simulations based on coupled Heat, Air and Moisture transport, even in a simplified situation.
- The simulation results are sensitive to the imposed boundary conditions and solver settings.

Conclusions

Future work

- Future steps in this study will include performing a grid-sensitivity analysis and re-evaluate the validation of the model based on extensive experimental data.
- Influence of solar radiation as short-term fluctuation on indoor climate conditions.
- Couple indoor climate as boundary condition to a stress-strain model of typical heritage objects.
